Deterministic zero search and optimization

- **Zero search:** One aims at finding a zero θ^* of a function $h : \mathbb{R}^d \rightarrow \mathbb{R}^d$. In view of generic notations in stochastic approximation, we will denote

$$h(\theta), \theta \in \mathbb{R}^d$$

rather than $h(x)$.

($d = 1$ is mandatory just for graphs).

- Various methods (I):
 - **Local recursive zero search** (standard): θ_0 be fixed and let $\gamma > 0$ be small enough. Set

$$\theta_{n+1} = \theta_n - \gamma h(\theta_n), \quad n \geq 0$$

- Various methods (II):

- **Local recursive zero search**. If h is $\mathcal{C}^1$ (Newton-Raphson “false position” algorithm)

$$\theta_{n+1} = \theta_n - [J_h(\theta_n)]^{-1} h(\theta_n), \quad n \geq 0,$$

where $J_h(\theta)$ denotes the **Jacobian** of h at θ .

Idea: The tangent hyperplane is the best approximation of h (by an affine function)

$$h(\theta) \simeq h(\theta_n) + J_h(\theta_n)(\theta - \theta_n)$$

so that θ_{n+1} is solution to $h(\theta_n) + J_h(\theta_n)(\theta - \theta_n) = 0$.

Very fast but also very unstable, especially when $J_h(\theta^*)$ is “small”.

- **Yet another local recursive zero search** if $h \in \mathcal{C}^1$ (Levenberg-Marquardt algorithm): Let $\lambda_n > 0$, $n \geq 1$,

$$\theta_{n+1} = \theta_n - [J_h(\theta_n) + \lambda_{n+1} I_d]^{-1} h(\theta_n), \quad n \geq 0.$$

turns out to be more stable... by an appropriate choice of λ_n .

- Various methods (III):
 - Global recursive zero search:
 - Idea: make the step decrease (not too fast) to “enlarge” in an adaptive way the convergence area of the algorithm...
 - Let $\gamma_n, n \geq 1$ satisfy

$$\sum_{n \geq 1} \gamma_n = +\infty \text{ and } \sum_{n \geq 1} \gamma_n^2 < +\infty.$$
 - Set

$$\theta_{n+1} = \theta_n - \gamma_{n+1} h(\theta_n), \quad n \geq 0.$$
- To be continued...
- BUT **WARNING!** All these methods require

h can be computed at a reasonable cost.

Minimizing a (potential function)

- Gradient descent (GD):

Let $V : \mathbb{R}^d \rightarrow \mathbb{R}_+$, $\mathcal{C}^1$ with $\lim_{|x| \rightarrow +\infty} V(x) = +\infty$ so that

$\operatorname{argmin}_{\mathbb{R}^d} V \neq \emptyset$.

How to compute $\operatorname{argmin} \& \min_{\mathbb{R}^d} V???$

- If moreover V is **convex**, then

$$\operatorname{argmin}_{\mathbb{R}^d} V = \{\nabla V = 0\} \quad (\text{is a convex set})$$

– Solution: set $h = \nabla V$,

– If ∇V Lipschitz, then (exercise)

$$\theta_n \rightarrow \theta^* \in \{\nabla V = 0\} = \operatorname{argmin}_{\mathbb{R}^d} V \quad \text{as} \quad n \rightarrow +\infty.$$

- If V is **not convex** it often happens that

$$\operatorname{argmin} V \not\subseteq \{\nabla V = 0\}.$$

Still set $h = \nabla V$ (what else?)

- Pseudo-gradient (back to zero search!):

The function h is often given (model) and (hopefully) there exists a **Lyapunov function** V s.t. $(h|\nabla V) \geq 0$ and

$$\{h = 0\} \simeq \{(h|\nabla V) = 0\} \quad (\subset \text{ is ok!}).$$

If $(d = 2)$, $\mathcal{H}(V)(x) = \begin{pmatrix} -\partial_{x_2} V \\ \partial_{x_1} V \end{pmatrix}$ (**Hamiltonian of $\nabla V(x)$**) and

$$h(x) = \lambda \nabla V(x) + \mu \mathcal{H}(V)(x)$$

then, the above conditions are satisfied and $|h|^2$ has V -linear growth so that $\theta_n \rightarrow C(0; 1)$ (if $\theta_0 \neq 0$) but does not converge “pointwise”.

However, on this example, $V(\theta_n) \rightarrow \arg\min V$

- It may happen that $\{h = 0\} \neq \{(h|\nabla V) = 0\} \neq \{\nabla V = 0\} \neq \arg\min V$!!.

Implicitation: Implied Volatility

- Black-Scholes model: traded asset $X_t = x_0 e^{(r - \frac{\sigma^2}{2})t + \sigma W_t}$, $x_0 > 0$, volatility $\sigma > 0$, interest rate r , W standard Brownian motion.
- Call payoff $(X_T - K)^+ = \max(X_T - K, 0)$ with strike price K and maturity T .
- Mark-to-Market quoted price: $\text{Call}_{Mkt}(K, T) \in (0, x_0)$.
- Black-Scholes price at time 0

$$\begin{aligned}\text{Call}_{BS}(x_0, K, r, \sigma, T) &= e^{-rT} \mathbb{E} (X_T - K)^+ \\ &= x_0 \Phi_0(d_1) - K e^{-rT} \Phi_0(d_2) \\ d_1 &= \frac{\log(\frac{x_0}{K}) + (r + \frac{\sigma^2}{2})T}{\sigma \sqrt{T}}, \quad d_2 = d_1 - \sigma \sqrt{T}.\end{aligned}$$

- Implicitation of the volatility: solve in σ the inverse problem

$$\text{Call}_{BS}(\dots, \sigma, \dots) - \text{Call}_{Mkt}(K, T)(K, T) = 0.$$

- Graphs of $\sigma \mapsto \text{Call}_{BS}(\sigma)$, $\sigma \in \mathbb{R}$: In-, At- and Out- the money.

- The function is **symmetric** in σ so that the equation has two opposite solutions.
- As $\sigma < 0$ is meaningless, one considers on the whole real line $\mathbb{R}$,

$$\sigma \longmapsto \text{Call}_{BS}(\sigma^+)$$

where $\sigma^+ = \max(\sigma, 0)$.

- It becomes a **non-decreasing function**.

- Algo₁:

$$\sigma_{n+1} = \sigma_n - \gamma_{n+1} \underbrace{\left(\text{Call}_{BS}(x_0, K, r, \sigma_n^+, T) - \text{Call}_{Mkt}(K, T) \right)}_{=:h(\sigma_n)}, \quad \sigma_0 > 0,$$

with $\gamma_n = \gamma > 0$ or decreasing assumption.

- Algo₂ (Newton's zero search, hopefully) on the positive real line
 - The **Vega**: for $\dots \sigma \in \mathbb{R}$ (Warning!),

$$\text{Vega}_{BS}(\sigma) = \frac{\partial}{\partial \sigma} \text{Call}_{BS}(\sigma) = x_0 \text{sign}(\sigma) \sqrt{T} \frac{e^{-\frac{d_1(|\sigma|)^2}{2}}}{\sqrt{2\pi}}$$

- Implicit volatility search reads (works as long as $\sigma_n > 0 \dots$):

$$\sigma_{n+1} = \sigma_n - \underbrace{\frac{1}{\text{Vega}_{BS}(\sigma_n)}}_{=:h'(\sigma_n)} \underbrace{\left(\text{Call}_{BS}(x_0, K, r, |\sigma_n|, T) - \text{Call}_{Mkt}(K, T) \right)}_{=:h(\sigma_n)}, \quad \sigma_0 \in \mathbb{R}.$$

[This is the actual algorithm with the “good choice” of $\sigma_0 = \sqrt{\frac{2}{T} \left| \log \left(\frac{x e^{rT}}{K} \right) \right|}$ (inflection point!) **avoiding the negative side** and ensuring a fast convergence ⁽¹⁾. Otherwise it may converge either to σ_{impli} or $-\sigma_{\text{impli}}$]

¹S. Manaster, G. Koehler (1982). The calculation of Implied Variance from the Black–Scholes Model: A Note, *The Journal of Finance*, **37**(1):227–230

Implicitation: Implied Correlation I

- 2-dim (correlated) Black-Scholes model:

$$X_t^i = x_0^i e^{(r - \frac{\sigma_i^2}{2})t + \sigma_i W_t^i}, \quad x_0^i, \sigma_i > 0, i = 1, 2$$

with $\langle W^1, W^2 \rangle_t = \rho t$.

- Best-of-Call Payoff:

$$(\max(X_T^1, X_T^2) - K)^+.$$

- Premium at time 0

$$\text{Best-of-Call}_{BS}(\dots, \rho, \dots) = e^{-rT} \mathbb{E} (\max(X_T^1, X_T^2) - K)^+.$$

- Organized markets on such options are **market of the correlation ρ** .
- The volatilities σ_i , $i = 1, 2$, are known from vanilla option markets on X^1 and X^2 .

How to “extract” the correlation ρ ?

- Deterministic algo(s):

$$\rho_{n+1} = \rho_n - \gamma_{n+1} \underbrace{\left(\text{Best-of-Call}_{BS}(\rho_n) - \text{Best-of-Call}_{Mkt}(K, T) \right)}_{=: h(\rho_n)}.$$

or the Levenberg-Marquard variant of Newton's zero search algorithm

$$\rho_{n+1} = \rho_n - \frac{\text{Best-of-Call}_{BS}(\rho_n) - \text{Best-of-Call}_{Mkt}(K, T)}{\partial_{\rho} \text{Best-of-Call}_{BS}(\rho_n) + \lambda_n}.$$

- Except that we have no (simple) closed form for the B - S price and its ρ -derivative.
- The correlation $\rho \in [-1, 1]$. Projections are possible but....
- What to do?

Minimization: Value-at-risk/Conditional Value-at-risk/I

- Let $X = \varphi(Z)$, $Z : (\Omega, \mathcal{A}, \mathbb{P}) \rightarrow \mathbb{R}^q$ be an **integrable** random variable representative of a loss and let $\alpha \in (0, 1)$, $\alpha \simeq 1$.

$$\text{Value-at-Risk}_{\alpha}(X) = \alpha\text{-quantile} = \inf \{ \xi : \mathbb{P}(X \leq \xi) \geq \alpha \}.$$

- For simplicity, assume X has a density $f_X > 0$ on $\mathbb{R}$. Then $\xi_{\alpha} = \text{VaR}_{\alpha}(X)$ is the unique solution to

$$\mathbb{P}(X \leq \xi_{\alpha}) = \alpha \iff \mathbb{P}(X > \xi_{\alpha}) = 1 - \alpha.$$

- The conditional Value-at-Risk is defined by

$$\text{CVaR}_{\alpha}(X) := \mathbb{E}(X \mid X \geq \text{VaR}_{\alpha}(X)) = \frac{1}{1 - \alpha} \int_{\text{VaR}_{\alpha}(X)}^{+\infty} \mathbb{P}(X > u) du.$$

- Rockafellar-Uryasev Potential ⁽²⁾:

$$V_{\alpha}(\xi) = \xi + \frac{1}{1 - \alpha} \mathbb{E}(X - \xi)^+, \quad \xi \in \mathbb{R}.$$

²R.T. Rockafellar, S. Uryasev (2000). Optimization of Conditional Value-At-Risk, *The Journal of Risk*, 2(3):21–41.
www.ise.ufl.edu/uryasev.

- The function V_α is **convex** and $\lim_{|\xi| \rightarrow +\infty} V_\alpha(\xi) = +\infty$ since

$$V_\alpha(\xi) \geq \xi \quad \text{so that} \quad \lim_{\xi \rightarrow +\infty} V_\alpha(\xi) = +\infty$$

and

$$\begin{aligned} V_\alpha(\xi) &\geq \xi + \frac{1}{1-\alpha} (\mathbb{E} X - \xi)^+ && \text{by Jensen's inequality} \\ &\geq \xi + \frac{1}{1-\alpha} (\mathbb{E} X - \xi) \\ &= -\frac{\alpha}{1-\alpha} \xi + \frac{1}{1-\alpha} \mathbb{E} X \rightarrow +\infty && \text{as } \xi \rightarrow -\infty. \end{aligned}$$

- By exchanging differentiation and $\mathbb{E}$, we get

$$V'_\alpha(\xi) = 1 - \frac{1}{1-\alpha} \mathbb{P}(X > \xi).$$

- $V'_{\alpha}(\xi) = 0$ iff $\mathbb{P}(X > \xi) = 1 - \alpha$ iff $\xi = \xi_{\alpha}$.

- Moreover

$$\begin{aligned} V_{\alpha}(\xi_{\alpha}) &= \frac{\xi_{\alpha} \mathbb{P}(X > \xi_{\alpha}) + \mathbb{E}(X - \xi_{\alpha})^+}{\mathbb{P}(X > \xi_{\alpha})} = \frac{\mathbb{E} X \mathbf{1}_{\{X > \xi_{\alpha}\}}}{\mathbb{P}(X \geq \xi_{\alpha})} \\ &= \mathbb{E}(X | X \geq \text{VaR}_{\alpha}(X)) = \text{CVaR}_{\alpha}(X). \end{aligned}$$

- (GD) pour la $\text{VaR}_{\alpha}(X)$: $h(\xi) = V'(\xi)$. Let $\xi_0 \in \mathbb{R}$,

$$\begin{aligned} \xi_{n+1} &= \xi_n - \gamma_{n+1} \left(1 - \frac{1}{1 - \alpha} (1 - F_x(\xi_n)) \right) \\ &= \xi_n - \frac{\gamma_{n+1}}{1 - \alpha} (F_x(\xi_n) - \alpha), \quad n \geq 0. \end{aligned}$$

- Newton/Levenberg-Marquardt algo: $\xi_0 \in \mathbb{R}$,

$$\xi_{n+1} = \xi_n - \frac{F_x(\xi_n) - \alpha}{f_x(\xi_n) + \lambda_n(?)}, \quad n \geq 0.$$

- Why not ! But $X = \varphi(Z)$ (the whole portfolio of a CIB Bank!) $\Rightarrow q$ large and no closed form for the c.d.f. $F_x(\xi) = \mathbb{P}(X \leq \xi)$ of X .
